AI Assistant Coding

Lab - 7.1

Question 1:

Task Description #1 (Syntax Errors – Missing Parentheses in Print Statement)
Task: Provide a Python snippet with a missing parenthesis in a print statement (e.g., print "Hello"). Use AI to detect and fix the syntax error.
# Bug: Missing parentheses in print statement
def greet():
print "Hello, AI Debugging Lab!"
greet()
Requirements:
• Run the given code to observe the error.
• Apply AI suggestions to correct the syntax.
• Use at least 3 assert test cases to confirm the corrected code works.
Expected Output #1:
• Corrected code with proper syntax and AI explanation.

Prompt :

```
# Bug: Missing parentheses in print statement
```

Code :

```
def greet():
    print("Hello! Welcome to the Python programming lab.")
greet()
```

Output :

```
-Coding\lab6.py"
Hello! Welcome to the Python programming lab.
PS C:\Users\dasar\AI-Assistant-Coding>
```

Analysis :

The error occurs due to missing parentheses in the `print` statement, which is invalid in Python 3. After correction, the function executes correctly as verified by assert test cases.

Question 2:

Task Description #2 (Incorrect condition in an If Statement)
Task: Supply a function where an if-condition mistakenly uses =
instead of ==. Let AI identify and fix the issue.
# Bug: Using assignment (=) instead of comparison (==)
def check_number(n):
if n = 10:
return "Ten"
else:
return "Not Ten"
Requirements:
• Ask AI to explain why this causes a bug.
• Correct the code and verify with 3 assert test cases.
Expected Output #2:
• Corrected code using == with explanation and successful test
execution

Prompt :

```
# Explain why the if-condition causes a bug. Correct the code. Verify
the corrected code using at least 3 assert statements.
def check_number(n):
if n = 10:
    return "Ten"
else:
    return "Not Ten"
```

Code :

```
# The if-condition causes a bug because it uses a single equals sign
(=) which is an assignment operator instead of a double equals sign
(==) which is a comparison operator. This will result in a syntax
error. The corrected code is as follows:
def check_number(n):
    if n == 10:
        return "Ten"
    else:
        return "Not Ten"
# Verify the corrected code using assert statements
assert check_number(10) == "Ten", "Test case 1 failed"
```

```
assert check_number(5) == "Not Ten", "Test case 2 failed"
assert check_number(0) == "Not Ten", "Test case 3 failed"
print("All test cases passed!")
```

Output :

```
PS C:\Users\dasar\AI-Assistant-Coding> python -u "c:\Users\dasar\AI-Assistant-Coding\l
b6.py"
All test cases passed!
PS C:\Users\dasar\AI-Assistant-Coding>
```

Analysis :

The bug is caused by using the assignment operator (=) instead of the comparison operator (==). Fixing this allows correct conditional checking, confirmed through assert tests.

Question 3:

Task Description #3 (Runtime Error – File Not Found)
Task: Provide code that attempts to open a non-existent file and crashes. Use AI to apply safe error handling.
# Bug: Program crashes if file is missing
def read_file(filename):
with open(filename, 'r') as f:
return f.read()
print(read_file("nonexistent.txt"))
Requirements:
• Implement a try-except block suggested by AI.
• Add a user-friendly error message.
• Test with at least 3 scenarios: file exists, file missing, invalid path.
Expected Output #3:
• Safe file handling with exception management

Prompt :

```
#Identify the runtime error. Apply safe error handling using
try-except. Add a user-friendly error message. Test the function for:-
file exists- file missing - invalid file path
Code:
def read_file(filename):
    with open(filename, 'r') as f:
        return f.read()
print(read_file("nonexistent.txt"))
```

Code :

```
# The runtime error occurs because the file "nonexistent.txt" does not
exist. To handle this error safely, we can use a try-except block to
catch the FileNotFoundError and provide a user-friendly error message.
Here is the corrected code:
def read_file(filename):
    try:
        with open(filename, 'r') as f:
            return f.read()
    except FileNotFoundError:
        return f"Error: The file '{filename}' does not exist. Please
check the file path and try again."
# Test the function for different scenarios
print(read_file("existing_file.txt"))  # Assuming this file exists
print(read_file("nonexistent.txt"))  # This file does not exist
print(read_file("/invalid/path/to/file.txt"))  # Invalid file path
```

Output :

```
Error: The file 'existing_file.txt' does not exist. Please check the file path and try
again.
Error: The file 'nonexistent.txt' does not exist. Please check the file path and try ag
ain.
Error: The file '/invalid/path/to/file.txt' does not exist. Please check the file path
and try again.
PS C:\Users\dasar\AI-Assistant-Coding>
```

Analysis :

The program crashes when a file is not found due to missing exception handling. Using `try-except` prevents runtime failure and provides safe file access.

Question 4:

Task Description #4

Task: Give a class where a non-existent method is called (e.g., obj.undefined_method()). Use AI to debug and fix.
# Bug: Calling an undefined method
class Car:
def start(self):
return "Car started"
my_car = Car()
print(my_car.drive()) # drive() is not defined
Requirements:

• Students must analyze whether to define the missing method or correct the method call.
• Use 3 assert tests to confirm the corrected class works.
Expected Output #4:
• Corrected class with clear AI explanation

Prompt :

```
#Debug the following Python class.Identify the error and explain
it.Decide whether to define the missing method or fix the method
call.Provide corrected code.Add at least 3 assert test cases.
Code:
class Car:
    def start(self):
        return "Car started"

my_car = Car()
print(my_car.drive())
```

Code :

```
# The error occurs because the method 'drive()' is called on the
'my_car' object, but the 'Car' class does not have a method named
'drive()' defined. To fix this, we can either define the 'drive()'
method in the 'Car' class or change the method call to a method that
exists (like 'start()'). In this case, we will define the 'drive()'
method in the 'Car' class.
class Car:
    def start(self):
        return "Car started"
    def drive(self):
        return "Car is driving"
my_car = Car()
print(my_car.drive())
```

Output :

```
PS C:\Users\dasar\AI-Assistant-Coding> python -u "c:\Users\dasar\AI-Assistant-Coding\la
b6.py"
Car is driving
PS C:\Users\dasar\AI-Assistant-Coding>
```

Analysis :

The error occurs because a non-existent method is called on the object. Defining the missing method resolves the issue and ensures correct class behavior.

Question 5:

Task Description #5 (TypeError – Mixing Strings and Integers in Addition)
Task: Provide code that adds an integer and string ("5" + 2) causing a TypeError. Use AI to resolve the bug.
# Bug: TypeError due to mixing string and integer
def add_five(value):
return value + 5
print(add_five("10"))
Requirements:
• Ask AI for two solutions: type casting and string concatenation.
• Validate with 3 assert test cases.
Expected Output #5:
• Corrected code that runs successfully for multiple inputs.
Note: Report should be submitted a word document for all tasks in a single document with prompts, comments & code explanation, and output and if required, screenshots

Prompt :

```
#The following code raises a TypeError.Explain why the error
occurs.Provide TWO solutions:a) Using type castingb) Using string
concatenationValidate both solutions with at least 3 assert test cases
Code:
def add_five(value):
    return value + 5

print(add_five("10"))
```

Code :

```python
# The TypeError occurs because the function 'add_five' is trying to add
an integer (5) to a string ("10"), which is not allowed in Python. To
fix this, we can either use type casting to convert the string to an
integer before performing the addition or use string concatenation to
combine the string with "5". Here are both solutions:
# Solution a) Using type casting
def add_five_casting(value):
    return int(value) + 5
# Solution b) Using string concatenation
def add_five_concatenation(value):
    return value + "5"
# Validate both solutions with assert test cases
# Test cases for type casting solution
assert add_five_casting("10") == 15, "Test case 1 failed"
assert add_five_casting("0") == 5, "Test case 2 failed"
assert add_five_casting("-5") == 0, "Test case 3 failed"
# Test cases for string concatenation solution
assert add_five_concatenation("10") == "105", "Test case 1 failed"
assert add_five_concatenation("0") == "05", "Test case 2 failed"
assert add_five_concatenation("-5") == "-55", "Test case 3 failed"
print("All test cases passed for both solutions!")
```

Output :

```
PS C:\Users\dasar\AI-Assistant-Coding> python -u "c:\Users\dasar\AI-Assistant-Coding\la
b6.py"
All test cases passed for both solutions!
PS C:\Users\dasar\AI-Assistant-Coding>
```

Analysis :

The TypeError occurs due to adding a string and an integer. Type casting and string concatenation both resolve the issue and work correctly for multiple inputs.
